Corn Yield Response to Nitrogen Rate - Metamora
Eric Richer, Ohio State University Extension Educator, Fulton County, Ohio

Objective
To determine the effects of nitrogen rate on corn grain yield and profitability.

Background
Crop Year: 2016  Tillage: Fall disc rip f.b. spring finisher
County: Fulton  Soil Test (grid avg):pH 5.7
Location: Metamora, Ohio  P 31 ppm (Bray-P1)
Drainage: systematic, 40’ laterals  K 123 ppm
Previous Crop: Soybeans  O.M. 2.1%
Variety: Great Lakes 5470  CEC 6.9 meq/100g
Population: 34,200 seeds per acre  Starter Fertilizer: 21-31-150/ac
Plant Date: May 8, 2016  Pre-Sidedress Nitrogen Test: 9 ppm NO3-N
Harvest Date: October 24, 2016  Nitrogen Source: Anhydrous Ammonia
Herbicide: Capreno and Atrazine (Post-emerge)  Rainfall (May – August): 14.3”
Soil Type: Brady, Millgrove

Methods
Five corn nitrogen rates were replicated four times in a randomized complete block design. Plots were 16 rows wide (40 feet) by 1320 feet long. The trial was planted, sprayed and harvested with commercial farm equipment. The treatments were made with commercial nitrogen application equipment. All treatment received 21 units of nitrogen at plant and the balance of the total nitrogen rate at sidedress during growth stage V5-V6. A corn stalk nitrate test (CSNT) was taken for every replication and then averaged. Yields and moistures were measured using a calibrated yield monitor and shrunk to 15% moisture. Precipitation data was recorded by the farmer.

LSD (P<.05, CV 1.23) = 3.56

* 21 lbs/ac rate was unreplicated, planter applied only; not used in discussion.
**Based on $3.50/bu corn and $.42/lb N (Source: OSUE 2016 Corn Budget)
Discussion:
There was a statistical significant difference for yield among the 4 replicated nitrogen rates at this site in 2016. The highest statistically significant yield was 193 bu/ac using a total nitrogen rate of 300 lbs/ac. The lowest statistically significant replicated yield was 164.8 bu/ac using a total nitrogen rate of 75 lbs/ac. A CSNT indicates that optimal nitrate-N concentrations were achieved at the 225-300 lbs/ac rate, but rates of 150 lbs/ac and lower could have been yield limiting.

However, a standard economics calculation shows that the maximum economic return rate is 150 lbs of total nitrogen, netting $572/acre after nitrogen cost. At the economic optimum rate, the commercial nitrogen use efficiency (NUE) proved to be .83 lb of nitrogen per bushel of corn.

Economic optimum nitrogen rates vary greatly by nitrogen cost, corn price, soil type, rainfall timing and amounts, application practices and other factors. Conducting nitrogen rate trials on a specific farm is the best way to determine the economic optimum rate for that farm.

Acknowledgement
The author wishes to express appreciation to on-farm collaborator Scott Conrad for conducting this trial. Thanks to agronomy intern Ben Eggers for assistance with data collection. Thanks to the Culman Lab at OARDC for processing CSNT tests and to the Ohio Corn Checkoff Board for supporting this research.

Table 2. Nitrate Concentration Categories

<table>
<thead>
<tr>
<th>Nitrate-Nitrogen ppm</th>
<th>Rating</th>
<th>Interpretations+</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 250</td>
<td>Low</td>
<td>Nitrogen was likely yield limiting during the growing season, especially if the test result is less than 250 ppm.</td>
</tr>
<tr>
<td>250-2,000</td>
<td>Optimal</td>
<td>Grain yield was not limited by the amount of nitrogen available to the crop. Note: the high end of this category is appropriate when nitrogen prices are low and corn prices high. The low end of this category is appropriate when nitrogen prices are high and corn prices low.</td>
</tr>
<tr>
<td>Greater than 2,000</td>
<td>Excess</td>
<td>Excessive nitrogen available to the crop, or some other production factor limited crop growth and yield.</td>
</tr>
