Corn Tillage System Comparison

Alan Sundermeier, Agriculture and Natural Resources Extension Agent
Matt Davis, OARDC NW Branch Manager

Objective
To evaluate the effect of tillage systems on yield of corn.

Background

Cooperator: NW Branch
Fertilizer: See Methods
County: Wood
Planting Date: May 29, 2002
Nearest Town: Deshler
Planting Rate: 30,000 seed/acre
Drainage: Tile, well-drained
Row Width: 30-inch
Soil type: Hoytville, clay
Herbicides: Harness Extra 2.4 qt/A, Atrazine 1 pt/A
Previous Crop: Soybeans
Harvest Date: October 23, 2002

Methods

The entries were replicated four times in a randomized complete block design. Plot size was 10 x 70 feet, each entry. After the 2001 soybean harvest, the following fertilizer was applied: 100 lbs/A of 0-46-0 and 150 lbs/A of 0-0-60. On 11-05-01, fall tillage was performed on the soybean residue: strip-tillage, Aer-Way and Harrow, Zone-builder, and disk and field cultivator (stale seedbed). The remaining entry was untouched for no-till.

No further tillage was done, and corn was directly planted into soil as is in the spring (no spring tillage). At corn planting, 20 lbs/A of 46-0-0 was placed 2 x 2. Sidedress application of 43 gal/A of 28-0-0 was coulter injected in June. Harvest data were collected from the center two rows.

Results

Table 1. Corn Yield by Tillage System

<table>

Summary

Yields were extremely low due to late planting (May 29) followed by a lack of rainfall during the summer growing season. For that reason, no meaningful conclusions should be derived comparing the tillage systems.

Zone builder tillage (subsoiler) may have allowed the soil to dry out more than the other systems due to its 12- to 18-inch deep shank penetration, thus resulting in lower yields. This was consistent with results from other research at the same site in 2002.

Disking and field cultivation in the fall was in the highest-yielding group of treatments, but it also had the least amount of surface residue for soil protection from erosion.
