Soybean Population Study, Darke County

Samuel G. Custer, Ohio State University Extension Educator, Darke County

Objective
To determine the effects of soybean seeding rate on soybean yields that will provide data for determining BMPs for soybean seeding rates and may provide data points for determining variable rates for soybean seeding.

Background
Crop Year: 2017
Location: Adams Township
County/Town: Darke/Bradford
Soil Type: Celina Silt Loam
Brookston Silty Loam
Drainage: Systematic Pattern
Previous Crop: Corn
Tillage: No-Till
Soil Test: pH 6.3, P 24 ppm BP1, K 129 ppm
Planting Date: May 16, 2017
Seeding Rate: Varied
Harvest Date: October 3, 2017
Rainfall: 26.66 in. - 4/15-9/15

Methods
Five soybean populations were replicated three times in a randomized complete block design. Treatments were planted with a 12 row Kinze planter with split row units (resulting in 15 inch row spacing) 500 feet in length. All treatments received the same tillage and herbicide applications. Varieties used in a split planter were Asgrow 3832 and 38X2. Stand counts were taken at V4 by obtaining 2 counts using 1/1,000th of an acre per treatment and calculating the simple average. Plots were harvested with a commercial combine equipped with a 30 foot grain header. Yields and moistures were obtained by using a calibrated yield monitor. Yields were verified using a grain cart. Yields were adjusted to 13% moisture. Precipitation data were obtained from cocorahs.org and recorded daily.

CV % 5.06; Not significant, LSD = .1
Summary
As expected from previous research, which has shown that the soybean is adaptive in relation to planted population, soybean yield was not influenced by planting population.

Acknowledgement
The author expresses appreciation to on-farm collaborators Overholser Farms for the land use, planting and harvesting of this plot.
